Integrated well-log, VSP, and surface seismic analysis of near-surface glacial sediments shale/sandstone bedding. The character of the full-waveform sonic first arrival times has similarities to the other logs (Fig.3). We also shot 2D and 3D surface seismic surveys. There is a clear reflection at the red fracture zone at 35m depth.~~

The well logs included measurements of conductivity, radioactivity (gamma ray), temperature, and sonic velocity. Sonic and VSP velocities ranged from 1500m/s in the very near surface to 3000m/s at 85m depth. A distinct black clay layer (with high conductivity, high gamma ray, and low velocity) was penetrated at 85m.~~

This allows a direct correlation of surface seismic data as well as synthetic data to the well logs in depth. Because this particular VSP used an offset source, we have created an offset image - both for P waves and converted (PS) waves. These VSP images can also be correlated and integrated into the interpretation. Figure 8.~~

The results are high-resolution 2D and 3D P&S images that yield important structural and stratigraphic information which assists in reservoir delineation, including identification of faults and salt flanks, as well as enhancing AVO calibration and anisotropy detection. Integrated with surface seismic and well-logging data, Offset VSP data can be used to define and describe formation rock properties / pore pressure indicators, and identify other reservoir details with very high resolution.~~

~~Offset Vertical Seismic Profile VSP - Halliburton
A class of borehole seismic measurements used for correlation with surface seismic data, for obtaining images of higher resolution than surface seismic images and for looking ahead of the drill bit; also called a VSP.~~

~~vertical seismic profile | Oilfield Glossary
Purely defined, VSP refers to measurements made in a vertical wellbore using geophones inside the wellbore and a source at the surface near the well. In the more general context, VSPs vary in the well configuration, the number and location of sources and geophones, and how they are deployed.~~

~~VSP - Schlumberger Oilfield Glossary
The major difference between a VSP and a checkshot survey is that VSP data are recorded at much smaller spatial sampling intervals than checkshots. While a receiver may be moved a vertical distance of 200 60.96 m to 1000 ft 304.8 m (61 to 305 m) between checkshot levels, it should be moved no more than 50 15.24 m~~

The VSP and well-log data are integrated in an AVO interpretation of the Devonian Slave Paint Formation. Vertical seismic profiles (VSP's) are the only survey that can "see" below the current drilled depth, and can be used to predict the depth of overpressuerd zones, reducing the risk of blowouts. Integrated sonic logs are still needed to fix the precise location of formation tops on the VSP wiggle traces.~~
